Defining Effect Methods for Other Models

John Fox and Sanford Weisberg

June 7, 2018

The `effects` package in R is designed primarily to draw graphs that visualize a fitted response surface of a fitted model in problems with a linear predictor. Many modeling paradigms that can be fit with base R or contributed packages fit into this framework, including methods for linear, multivariate linear, and generalized linear models fit by the standard `lm` and `glm` functions and by the `svyglm` function in the `survey` package (Lumley, 2004); linear models fit by generalized least squares using the `gls` function in the `nlme` package (Pinheiro et al., 2016); multinomial regression models fit by `multinom` in the `nnet` package (Venables and Ripley, 2002); ordinal regression models using `polr` from the `MASS` package (Venables and Ripley, 2002) and `clm` and `clm2` from the `ordinal` package (Christensen, 2015); linear and generalized linear mixed models using the `lme` function in the `nlme` package (Pinheiro et al., 2016) and the `lmer` and `glmer` functions in the `lme4` package (Bates et al., 2015); and latent class models fit by `poLCA` in the `poLCA` package (Linzer and Lewis, 2011). This is hardly an exhaustive list of fitting methods that are based on a linear predictor, and we have been asked from time to time to write functions to use `effects` with this other fittig methods.

The default `Effect.default` may work with some modeling functions, as would objects of the class `gls` that we describe below in Section 1. This will will work if your function recognizes the defaults for the arguments in the `sources` list described in Section 1. If the defaults don't work, you will need to create your own `Effect` method or call `Effect.default` with your own value of `sources`.

The `effect` package has five functions that create the information needed for drawing effects plots, `Effect`, `allEffects`, `effect` and `predictorEffect` and `predictorEffects`. To add new modeling to the package only `Effect` needs to be written; the package will take care of all the other functions.

All the functions described below are included in the `effects` package. These can be used as templates for adding methods for other modeling types.

1 Generalized Least Squares (`nlme` package)

The `gls` function in the `nlme` package (Pinheiro et al., 2018) fits linear models via generalized least squares. A call to `gls` creates an object of class `gls`. The following function will allow usage of such objects with the `effects` package.

```
Effect.gls <- function(focal.predictors, mod, ...){
     args <- list(
       type = "glm",
       call = mod$call,
       formula = formula(mod),
       family = family(mod),
       link = NULL,
       coefficients = coef(mod),
       vcov = as.matrix(vcov(mod)))
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

This function sets an argument `sources` that is then passed to the default `Effect.default`. The argument `focal.predictors` will be used to pass the focal predictors to other methods. The `mod` argument is the name of the regression object that has been created. The `...` argument allows passing other arguments to the default method.

The argument `sources` to `Effect.default` contains the information needed in a list of up to five arguments:

`type` The `effects` package has three basic modeling functions: `type = "glm"`, the default, is used for functions with a univariate response and a linear predictor and possibly a link function. This class includes linear models, generalized linear models, robust regression, generalized least squares fitting, linear and generalized linear mixed effects models and many others. The `type = "polr"` is used for ordinal regression models, as in the `polr` function in the `MASS` package, and similar methods in Section 6. The The `type = "multinom"` for multinomial log-linear models as fit by the `multinom` function in `nnet`, and to polytomous latent class models created with the `poLCA` function in the `poLCA` package.

`call` The `Effect.default` method uses the call to harvest additional arguments that it needs, such as `data`, `subset` and `family`. These are used to compute fitted values, and to interpret the terms in the formula for the linear predictor. The default is `mod$call` for S3 objects and `mod@call` for S4 objects.

`formula` In most cases the formula for the linear predictor is returned by `formula(mod)`, the default, but if this is not the case the value of this argument should be the value of the formula for fixed effects.

`family` and `link` GLM-like models include a `family` specifying both an error distrubtion and a link function. If the call `family(mod)` returns a family, you do not need to specify either of these values. The `betareg` function, on the other hand, fixes the error distribution as a Beta distribution, but it does include a link function using a `link` arguement. In this case, you must specify the link function; see the `betareg` example in Section 5

below. If you have a family, but it is not returned by `family(mod)`, use the `family` argument to specify it.

At present, non-canonical families like the negative binomial with two parameters in the variance function are not supported. This may be changed in the future.

`coefficients` In many cases the (fixed-effect) coefficient estimates are returned by `coef(mod)`, the default, but if this is not the case then the value of this argument should be the estimates of the coefficients in the linear predictor. The functions in the `effects` package do not use estimates of random effects.

`vcov` In many cases the estimated covariance matrix of the (fixed-effect) coefficient estimates is returned by `vcov(mod)`, the default, but if this is not the case then the value of this argument should be the estimated covariance matrix of the (fixed-effect) coefficient estimates in the linear predictor.

Since the values of all the arguments in `sources` are default values for the `gls` function, there is no need to have written the `Effect.gls` method, as the default method would work.

2 Mixed Effects with `lme` (`nlme` package)

The `lme` function in the `nlme` package (Pinheiro et al., 2018) fits linear mixed models. The required function for fitted objects from this function to be used with `effects` functions is

```
Effects.lme <- function(focal.predictors, mod, ...){
     args <- list(
       call = mod$call,
       formula = mod$call$fixed,
       coefficients = mod$coefficients$fixed,
       vcov = mod$varFix)
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

The `formula`, `coefficients` and `vcov` arguments do not have the default values, but an be obtained from the fitted model `mod` as shown. The `link` entry in `sources` is not used b `lme` and is given its default value of `NULL`. The `call` argument is set to be its default value.

3 Mixed Effects with the `lmer` (`lme4` package)

The `lme4` package (Bates et al., 2015) fits linear and generalized linear mixed effects models with the `lmer` and `glmer` functions, respectively. The same `Effect` function can be used for `lmer` and `glmer` models.

The following method is a little more complicated because it contains an additional argument `KR` to determine if the Kenward-Roger coefficient covariance matrix is to be used to compute effect standard errors. The default is `FALSE` because the computation is very slow. If `KR = TRUE`, the function also checks if the `pbkrtest` package is present.

```
Effect.merMod <- function(focal.predictors, mod, ..., KR=FALSE){
     if (KR && !requireNamespace("pbkrtest", quietly=TRUE)){
       KR <- FALSE
       warning("pbkrtest is not available, KR set to FALSE")}
     fam <- family(mod)
     args <- list(
       call = mod@call,
       coefficients = lme4::fixef(mod),
       vcov = if (fam == "gaussian" && fam$link == "identity" && KR)
         as.matrix(pbkrtest::vcovAdj(mod)) else as.matrix(vcov(mod)))
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

Because `lmer` is an S4 object (tested using the `isS4` function), the default for `call` is `mod@call`, and this argument would have been set authomatically had we not included it in the above fucntion. The `coefficient` for an object created by a call to `lmer` or `glimer` are not returned by `coef(mod)`, so the value of `coefficients` is the value returned by `lme4::fixef(mod)`. The `vcov` estimate contains its estimated variance covariance matrix of the fixed effects.

The `formula` for a mixed-effects model in the `lme4` package specifies both the linear predictor in the mean function and the linear predictor(s) in the variance functions in terms with parentheses and and vertical bars such as `(1 + age | subject)`. The `effects` code will automatically remove any terms like these in any formula.

4 Robust Linear Mixed Models (`robustlmm` package)

The `rlmer` function in the `robustlmm` package (Koller, 2016) fits linear mixed models with a robust estimation method. As `rlmer` closely parallels the `lmer` function, an object created by `rlmer` is easily used with `effects`:

```
Effect.rlmerMod <- function(focal.predictors, mod, ...){
     args <- list(
       coefficients = lme4::fixef(mod))
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

5 Beta Regression

The `betareg` function in the `betareg` package (Grün et al., 2012) fits regressions with a link function but with Beta distributed errors.

```
Effect.betareg <- function(focal.predictors, mod, ...){
     coef <- mod$coefficients$mean
     vco <- vcov(mod)[1:length(coef), 1:length(coef)]
     args <- list(
       call = mod$call,
       formula = formula(mod),
       coefficients = coef,
       link = mod$link$mean,
       vcov = vco)
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

The Beta distributions require estimation of the parameters of the Beta, but these are not used by `Effect`. The relevant coefficients and covariance matrix are extracted by the first two lines of the function. This method has a link function specified by the `link` argument, but no family, so the `link` argument is added to `sources`.

6 Ordinal Models (`ordinal` package)

Proportional odds logit and probit regression models fit with the `polr` function in the `MASS` package (Venables and Ripley, 2002) are supported in the `effects` package. The `ordinal` package, (Christensen, 2015) contains three functions that are very similar to `polr`. The `clm` and `clm2` functions allow more link functions and a number of other generalizations. The `clmm` function allows including random effects.

6.1 `clm`

```
Effect.clm <- function(focal.predictors, mod, ...){
     if (requireNamespace("MASS", quietly=TRUE)){
       polr <- MASS::polr}
     if(mod$link != "logit")
       stop("Effects only supports the logit link")
     if(mod$threshold != "flexible")
       stop("Effects only supports the flexible threshold")
     if(is.null(mod$Hessian)){
       message("\nRe-fitting to get Hessian\n")
       mod <- update(mod, Hess=TRUE)}
     numTheta <- length(mod$Theta)
     numBeta <- length(mod$beta)
```

```
  or <- c( (numTheta+1):(numTheta + numBeta), 1:(numTheta))
  args <- list(
    type = "polr",
    coefficients = mod$beta,
    vcov = as.matrix(vcov(mod)[or, or]))
  Effect.default(focal.predictors, mod, ..., sources=args)
}
```

This function first checks that the `MASS` package is available. Since the `clm` function allows suppressing the computation of the Hessian, the function checks and computes it if needed to get the estimated covariance matix. The `clm` function orders the parameters in the order (threshold parameters, linear predictor parameters), so the next few lines identify the elements of `vcov` that are needed by `Effects`. Since the `polr` function does not allow thresholds other thab `flexible`, we don't allow them either. Simiarly, we have only implemented effects for the default `logit` link.

6.2 clm2

```
Effect.clm2 <- function(focal.predictors, mod, ...){
  if (requireNamespace("MASS", quietly=TRUE)){
    polr <- MASS::polr}
  if(is.null(mod$Hessian)){
    message("\nRe-fitting to get Hessian\n")
    mod <- update(mod, Hess=TRUE)}
  if(mod$link != "logistic")
    stop("Effects only supports the logit link")
  if(mod$threshold != "flexible")
    stop("Effects only supports the flexible threshold")
  numTheta <- length(mod$Theta)
  numBeta <- length(mod$beta)
  or <- c( (numTheta+1):(numTheta + numBeta), 1:(numTheta))
  args <- list(
    type = "polr",
    formula = mod$call$location,
    coefficients = mod$beta,
    vcov = as.matrix(vcov(mod)[or, or]))
  Effect.default(focal.predictors, mod, ..., sources=args)
}
```

The syntax for `clm2` is not the same as `clm`, so a separate method is required.

6.3 clmm

This function allows for random effects in an ordinal model.

```
Effect.clmm <- function(focal.predictors, mod, ...){
     if (requireNamespace("MASS", quietly=TRUE)){
       polr <- MASS::polr}
     if(is.null(mod$Hessian)){
       message("\nRe-fitting to get Hessian\n")
       mod <- update(mod, Hess=TRUE)}
     if(mod$link != "logit")
       stop("Only the logistic link is supported by Effects")
     if(mod$threshold != "flexible")
       stop("Only threshold='flexible supported by Effects")
     numTheta <- length(mod$Theta)
     numBeta <- length(mod$beta)
     or <- c( (numTheta+1):(numTheta + numBeta), 1:(numTheta))
     skip <- length(unique(model.frame(mod)[,1])) - 1
     vcov <- matrix(NA, nrow=numBeta + skip, ncol=numBeta + skip)
     sel <- rownames(vcov(mod)) %in% names(mod$beta)
     vcov[1:numBeta, 1:numBeta] <- vcov(mod)[sel, sel]
     args <- list(
       type = "polr",
       formula = fixFormula(as.formula(mod$formula)),
       coefficients = mod$beta,
       vcov = as.matrix(vcov))
     Effect.default(focal.predictors, mod, ..., sources=args)
   }
```

Complications here come from getting the right elements of `vcov(mod)` corresponding to the fixed effects.

6.4 Others

The `poLCA` function in the `poLCA` package (Linzer and Lewis, 2011) fits polytomous variable latent class models, which uses the multinomial effects plots.

The `svyglm` function in the `survey` package (Lumley, 2004, 2016) fits generalized linear models using survey weights.
